

Examining the Effects of Gifted Classes on Mathematics and Reading/Language Arts Achievement

Proposal

This paper examines whether increased gifted instruction in the content areas of math and Reading/Language Arts (RLA) increases student achievement for gifted students in a large southern urban school district. Meta-analyses of grouping students into gifted classes shows increases in the achievement of gifted students (Steenbergen-Hu et al., 2016). In addition, many researchers have found that increasing the rigor of academic courses increases student achievement. However, only a few studies have used experimental or quasi-experimental designs to test the effectiveness of gifted education (Author, 2011; 2015; Gavin et al., 2007; 2009). Although these studies present experimental evidence of positive effects of exposure to enriched academic instruction on gifted student achievement, a propensity score matching analysis of Early Childhood Longitudinal Study data found no evidence of a positive effect of gifted education for gifted students and no negative effect for non-gifted students (Adelson, 2012). Our study uses new evidence and a quasi-experimental design to deepen our understanding of the effects of gifted classes on achievement.

Methods

To evaluate the impact of gifted classes on the achievement of students, we compare the RLA and mathematics achievement of gifted students in three different settings: schools offering a fulltime gifted-only program with gifted classes in all subject areas, schools offering a part-time gifted-only program with gifted classes in mathematics, and schools offering a part-time gifted-only program with gifted classes in RLA. In part-time programs, students attend gifted classes in their school's focal content area and are in general education classes for other content areas. Therefore, we can compare the RLA and mathematics achievement of gifted students in gifted classes to the achievement of gifted students in general education classes.

We conducted six sets of analyses: a simple comparison of students' fifth-grade achievement in schools of each program type using a bivariate OLS, an OLS estimate with additional covariates, propensity score matching analyses with and without covariates, and multilevel matching with and without covariates.

The naïve OLS model served as a point of comparison; however, we expected the results of the standard OLS to be biased, due to selection issues. Students and schools with different program models might vary by socioeconomic status (SES), early academic achievement, English learner (EL) status, and demographic characteristics. To address this potential source of bias, our second set of analyses tested the effects of gifted instruction by adding a full set of covariates to the original OLS regression models.

However, OLS regression with covariates might not fully capture the differences between students and schools in different programs. It is possible that an OLS regression with covariates

could be biased if key confounding variables were not included in the OLS model. To address this issue, we employed propensity score weighting and a non-propensity score multilevel matching strategy.

In a third and fourth set of analyses, we used propensity score weighting with and without covariates to account for differences between the programs. In a fifth and sixth set of analyses, we used multilevel matching with and without covariates to control for differences between school and district. Our multilevel matching approaches address some recent critiques of propensity matching to better approximate a true experiment when using observational data (King & Nielson, 2019; Pimentel, Page, Lenard & Keele, 2018).

Data

This study used data from a large, ethnically, economically, and linguistically diverse urban school district in a state that mandates gifted education identification and programming. This district provided fulltime gifted programming or part-time gifted math or RLA instruction as a function of the school students attend, not student ability. The three types of gifted instructional delivery types in one district offered an ideal setting to examine the impact of gifted-only classes on identified gifted students.

We gathered administrative data for two cohorts of 4th graders in the district from 2015/16 and 2016/17. We gathered student data on gifted status, EL status, SES, and race/ethnicity, and 2nd-through-5th-grade achievement. Each cohort grade consists of over 20,000 students, with 16% gifted. Among 175 schools that had some gifted instruction, 47% of these schools provided fulltime instruction, 6% provided part-time math instruction, 17% provided part-time RLA instruction, and the remaining schools had gifted instruction taught by itinerant teachers or a mixed model that included some fulltime and some part-time instruction.

For both cohorts, we examined academic achievement scores in mathematics and RLA from 2nd through 5th grade, gifted student status, student poverty (measured by free and reduced-price lunch status (FRPL)), EL status, and student race/ethnicity for each student. We also examined school average socioeconomic status, percent gifted, percent EL, average school academic achievement, and the racial/ethnic composition of the school.

Results

Our quantitative analysis revealed no discernable effects of gifted classes on either grade-level mathematics or RLA achievement (see Tables 3 and 4).

- There were no differences in RLA and math achievement across the various types of program offerings after controlling for the number of FRPL students in the school (see Tables 3 and 4).
- When we repeated these analyses with gain scores instead of 5th-grade achievement as the dependent variable, our results were similar (see Tables 3 and 4).

- There were no differences between gifted and general classes in math or RLA achievement in propensity score or multilevel matching models.
- Part-time RLA schools have lower levels of math achievement and higher levels of student poverty compared to fulltime and part-time math schools for all grades and cohorts (see Figures 2-5).
- Schools with part-time gifted math classes had lower levels of student poverty than full-time and part-time RLA schools. Our analysis of the descriptive characteristics between treatment and control groups found that there were large differences between schools and students in these two groups (see Tables 1-2). Our attempt to improve balance with weighted propensity score matching had only limited success. In contrast, multilevel matching provided a good balance between treatment and control groups with a standardized difference of .2 or less for most comparisons. However, this improved balance was at the cost of a dramatic reduction in sample size (see Tables 1-2).
